ABSTRACT

Objectives:
- To develop mono and bisyllabicspeech recognition audiometry lists in Moroccan dialect with corresponding picture boards adapted to morrocan children from 3 to 5 years old.
- To develop and record children's speech recognition audiometry lists in Moroccan dialect, adapted to children aged 6 and over.
- To test these lists on a sample of normal hearing Moroccan children in order to evaluate their reliability and validate them.

Materials and Methods: First of all, the linguistics laboratory created lists of monosyllabic et dissyllabic words in Moroccan dialect based on the Arabic speech audiometry lists. Then they created picture boards adapted to the lists.

**Corresponding author: E-mail: m.loudghiri@hotmail.com;*

The 2nd step was to validate this lists (word lists and picture boards) within a sample of normal hearing Moroccan children: This involved verifying that tonal audiometry was normal, then verifying that the words selected were common and well-known to children of this age, and finally verifiying that the pictures selected were well-know and adapted to the words.
During the study, the world lists and picture boards were tested in a university hospital otolaryngology service (Hospital 20 Août of Casablanca)and corrected (84 enfants).
Results: Twenty illustrated speech recognition audiometry lists intended for moroccan children from 3 to 5 years old and 20 recorded speech recognition audiometry lists intended for moroccan children from 6 years old was created.
All recorded words/pictures and words have been recognized by the children. The 40 lists evaluated made it possible to collect audiometry results speech consistent with the results of pure-tone audiometry.
Conclusion: At the end of this study, 20 illustrated speech recognition audiometry lists intended for moroccan children from 3 to 5 years old and 20 recordedspeech recognition audiometry lists intended for moroccan children from 6 years old have been validated in normal-hearing children. This is a first step before the validation of these lists in deaf children and by extension in children with cochlear implants.

Keywords: Audiometery; bisyllabic; monosyllabic; psychomotor development.

1. INTRODUCTION

Subjective audiometry allows the exploration of the different auditory pathways with the help of an acoustic stimulus. In children, it must take into account a certain number of parameters whose combination determines different audiometric strategies. This is called behavioral audiometry.

Pure tone audiometry explores hearing with a sound stimulus made of pure tones, voice audiometry requires the use of well-chosen words to complete the hearing exploration tests [1-3].

Indeed, voice audiometry in children has several interests in clinical practice, including:

A diagnostic interest: It confirms the results of the tonal audiometry by making it possible to control it and predicts the participation of the perception apparatus each time there is a deformation of the intelligibility curve.

A social interest: The deafness disturbs the deaf child, and can affect his school life, but the tonal audiometry can only give an idea on the depth of deafness and the possible site of hearing impairment but cannot assess the social problems that the deaf child may encounter in his daily life, this is the case for children with either a language delay or speech disorders or a delay in school / hyperactivity in which the diagnosis of deafness has gone unnoticed.

Behavioral audiometry allows us to show several cases of patients who have only a minimal hearing loss in tonal audiometry, but who present serious problems of intelligibility and speech comprehension. This is the case of central hearing impairment that can be seen in late onset genetic deafness.

An interest in the follow-up: In the post-operative follow-up, speech audiometry objectifies and quantifies the hearing gain after surgery. It is particularly useful for children in post cochlear implant follow-up.

A prosthetic interest: Speech audiometry allows audio prosthesisto judge the prosthetic possibilities much better than with the information obtained by tone audiometry and also helps in the prosthetic adjustments.

In our daily practice, the majority of Moroccan otologists do not use this voice audiometry test in children. This is mainly due to the fact that the word lists are not adapted to the child: words not used or not known by the child.

1.1 Objectives

This study has 3 objectives:

- To elaborate mono and bi-syllabic speech recognition audiometry lists in Moroccan dialect, adapted to children from 3 to 5 years old, which can be represented by corresponding picture boards, allowing the screening of auditory disorders in children from 3 years' old who cannot repeat the word, must be able to point to the corresponding picture.

- Develop and record monosyllabic and bi-syllabicspeech recognition audiometry lists in Moroccan dialect, adapted to children aged 6 years and older, who will be able to recognize and repeat them in recorded voice.
- To test these lists on a sample of normal hearing Moroccan children in order to evaluate their reliability and to validate them.

2. MATERIALS AND METHODS

2.1 Elaboration of Speech Recognition Audiometry Lists Adapted to the Child

The elaboration of speech recognition audiometry listswas based on lists in the literature,

The Design of the lists was made according to 2 populations: group A (children between 3 and 5 years old), group B (children 6 years old and more)

For the choice of words: the words were first written in Arabic letters, translated according to their meaning in French, then transcribed according to the international phonetic transcription.

For the conception of the lists: the words were divided according to the number of syllables, the syllabic architecture, and the lexical field. A proportional count of these different parameters was calculated and distributed equally between each list. The phonetic complexity index was respected as proposed by Jakielsky (2000).

2.2 Recording of the Lists

The recording of the words was done by professional voice-overs (male and female voices), in a professional studio, and with the collaboration of a sound engineer, in accordance with the ISO 8253-3 standard, the words, thereafter, were integrated into an audiogram, of the brand AD629 of Interacoustics.

2.3 Development of Picture Boards

Picture identification is a widely used technique for the description of children's known vocabulary, this technique based on pictures representing objects that we make sure during the pretest are known to the child, allows us to detect auditory difficulties if the child has not heard the word and hesitates to point out the corresponding object. The lists intended for the children of group A (aged 3 to 5 years).

Weconstituted 10 boards of recognizable images from the age of three years (Fig. 1).

Fig. 1. Example of images developed for the children's lists

The constraints were representability: excluding all abstract words, and simplicity of identification: the images had to have only one common name (the unknown images were changed by other more significant ones) (Fig. 2).

Fig. 2. Example of changed pictures

2.4 Evaluation of the Lists

For the evaluation of these lists, 84 normal hearing children aged 3 to 12 years were recruited at the ENT department of University Hospital 20 August in Casablanca. The tests were performed in an audiometric booth and room as quiet as possible, with an audiometer and built-in microphone connected to two loudspeakers. The word lists (Fig. 3) were tested within the 84 children.

The test was performed by an ENT doctor experienced in audiological testing of children (behavioral audiometry).

Fig. 3. Word lists

The reinforcement is the playful maneuver proposed to the child to encourage him to renew his answers. We used 3 types of conditioning: Verbal reward, PeeP Show, Embedding game.

3. RESULTS

We designed a total of 40 lists distributed as follows: 20 Lists for children aged 3 to 5 years: 10 monosyllabic lists of 10 words and 10 bissylabic lists of 10 words, and 20 lists for children aged 6 years and older: 10 monosyllabic lists of 14 words and 10 bissylabic lists of 10 words, and we included in our study 84 normal hearing children under 12 years of age.

3.1 Quantitative Results

Age: The average age was 6.4 years with extremes ranging from 3 to 12 years. The

population was divided into 2 age groups: Group A: age between 3 and 5 years (n=40) Group B: age between 6 and 12 years (n=44) The average age in group A was 4.2 years with extremes (5-3 years) and in group B was 8.3 years with extremes (12-6).

Schooling, 9.52% of the children were not in school, all were under 5 years old.

3.2 Audiometric Validation

On average, the time of realization of the tonal and vocal audiometric tests was 40 minutes with extremes ranging from 30 minutes to 60 minutes.

Group A: Pure tone audiometry was performed with headphones in 45% of the children (n=18) with a hearing threshold was between 10 and 20dBHL in 100%, and in free field in 55% of the children (n=22) the hearing threshold was between 15 and 30dB in 100% of the children, the S-shaped elongated speech audiometry curve was present in 100% of the cases.

Group B: Pure tone audiometry was performed with headphones in 100% of the children in group B (n=44), the hearing threshold was above 20dBHL in 100% of the children (n=44), the elongated S-shaped speech audiometry curve was present in 100% of the cases at the level of both ears combined.

3.3 Qualitative Results

10 lists of 10 monosyllabic words and 10 lists of 10 bisyllabic words were tested for group A. The identification difficulties were due to the same reasons: the word was not known to the child and despite the pretest the child could not repeat it, the image was not evocative enough and the child hesitated or made mistakes.

All words in the mono- and bisyllabic lists studied for Group B children were recognized and repeated at conversational thresholds.

4. DISCUSSION

Speech lists must meet a number of rules that differ according to each country's language. In the Arab Maghreb countries, HadiMessouak was the first to produce and publish phonetic material in Maghrebian Arabic for Tunisians, Algerians and Moroccans in 1956 [4]. In French-speaking countries, the most widely used lists for children are those of Lafon, but those of Fournier represent the basis of intelligibility tests [5]. In our study, we used the Moroccan monosyllabic and dissyllabic lists for adults, which we adapted to the child, taking into account all the stages of his oral, cognitive and motor development.

It is well know that children under the age of 5 can have a lack of vocabulary, so picture identification is a widely used technique for describing children's known vocabulary [6]. For an image to be easily recognized by the child, it must meet two criteria: representability and simplicity of identification.

We recorded the Voice material in accordance with ISO 8253-3 [7], it allows to have reliable and reproducible answers.

For a child to understand a word, several parameters must be involved: psychomotor development, hearing, cognitive and cultural aspects, linguistic aspects, intelligence, and mental reserve strength.

Development is often divided into specific domains, such as gross motor, fine motor, language, cognitive and developmental [8]. For this study, the children had a normal psychomotor development. And Behavioral audiometry allows to study the entire auditory field, especially the 250, 500 and 1000 Hz frequencies that are not always explored by conventional objective audiometry techniques, it guides the indication of objective tests, but It also provides information on the psychological behavior and communication level of the child [9].

In our study, the 3 means of conditioning were the Peep Show, the embedding game and the verbal reward.

The helmet is often poorly accepted by small children. We can then resort to the study of the threshold by air conduction in free field. This corresponds to the air conduction threshold of the better ear [9].

In our study, 55% of the children aged 3 to 5 years were tested in the free field compared to 45% in the headphones. Whereas 100% of the children aged 6 years and older adhered without difficulty to the headphones.

Voice audiometry: Voice audiometry is a complement to behavioral audiometry to verify the concordance of the results, and this from the age of 6 months. This examination is therefore essential to perform.

This audiometry involves understanding the message that induces a response, which varies according to the age of the child. The voice constitutes for the child a much more natural stimulus than pure sounds. It is recognized as a significant message depending on linguistic acquisitions [9].

That's why the adaptation of speech audiometry lists in children is necessary, especially in countries where the dialect differs from the official language, as is the case in China [10]. In the Maghreb, this study is the first one to be performed in children.

5. CONCLUSION

This work is an extension of a first study carried out by the ENT team of the University Hospital of Casablanca, which concerned the design and validation of Moroccan voice lists for adults.

Behavioral and vocal audiometry of small children requires a trained, patient, and attentive examiner.

At the end of this study, 20 illustrated voice lists for Moroccan children from 3 years of age and 20 recorded voice lists for Moroccan children from 6 years of age were validated in normal hearing children.

This is a first step before the validation of these lists in deaf children and by extension in cochlear implanted children.

CONSENT

Parental consent was signed prior to conducting the study.

ETHICAL APPROVAL

It is not applicable.

COMPETING INTERESTS

Authors have declared that no competing interests exist.
